Competition Law for State-Owned Enterprises

David E.M. Sappington†
J. Gregory Sidak††

State-owned enterprises (SOEs) can have strong incentives to engage in anticompetitive activities that serve to expand the scale and scope of their operations. Competition law for SOEs, however, is a body of jurisprudence to which U.S. courts and legislators have made little direct contribution. In contrast, the European Commission’s Deutsche Post decision in 2001 is an important step in the development of a competition law for SOEs. In this article, we develop a theoretical framework that explains why SOEs might engage in anticompetitive behavior. We propose a legal standard to analyze such behavior, and we argue that this standard should be more stringent than the legal standard applied to private firms. Although pricing below the greater of marginal cost or long-run average-incremental cost should be regarded as conclusive proof of predation by an SOE, a higher price floor generally is appropriate. The appropriate price floor varies with a number of economic factors that we identify.

I. INTRODUCTION

State-owned enterprises (SOEs), also known as public enterprises, are owned by governments rather than by private investors. SOEs compete directly with private, profit-maximizing enterprises in many important markets. For example, government postal firms often offer overnight mail and package shipping services in direct competition with private delivery companies. Many public hospitals and educational institutions compete directly with private suppliers of similar services. Production by public enterprises can be particularly widespread in developing countries. During the 1980s, for example, public enterprises accounted for approximately 14 percent of gross domestic product in African nations, and approximately 11 percent in developing countries as a whole.1

SOEs are typically instructed to pursue goals other than profit maximization. Therefore, one might suspect that SOEs would act less aggressively toward their competitors than would private, profit-maximizing firms. We will demonstrate, however, that the opposite often may be the case. Even though they may be less concerned with generating profit, SOEs may have stronger incentives than profit-maximizing firms to pursue activities that disadvantage competitors. Furthermore, these incentives can become more pronounced as the SOE’s concern with profit becomes less pronounced.2 These activities include setting prices below cost, misstating costs and choosing inefficient technologies to circumvent restrictions on below-cost pricing, raising the operating costs of existing rivals, and erecting entry barriers to preclude the operation of new competitors.

1. WORLD BANK, BUREAUCRATS IN BUSINESS: THE ECONOMICS AND POLITICS OF GOVERNMENT OWNERSHIP 30 (Oxford Univ. Press 1995). These statistics are consistent with earlier findings that, on average, public enterprises accounted for 8.6 percent of GDP and 27.0 percent of capital formation in the late 1970s. See R. P. Short, The Role of Public Enterprises: An International Statistical Comparison, in PUBLIC ENTERPRISES IN MIXED ECONOMIES: SOME MACROECONOMIC ASPECTS 118 (Robert Floyd, Clive Gray & R. P. Short eds., 1984). The corresponding percentages for Africa were 17.5 and 32.4, respectively. Id.

2. The discussion in this article draws from the analysis presented in David E.M. Sappington & J. Gregory Sidak, Incentives for Anticompetitive Behavior by Public Enterprises (AEI Working Paper, Nov. 2002), which contains formal mathematical proofs of the conclusions presented below in Part III.
Governmental policy objectives can induce SOEs to value an expanded operating scale. To illustrate, SOEs are often instructed to increase local employment and/or to ensure that affordable service is provided ubiquitously to low-income families. Such directives can blunt incentives for profit maximization, and thereby introduce a system in which the success of the manager of an SOE is measured more by the scale and scope of his operations than by the profit that his operations generate. Under such an explicit or implicit reward structure, SOEs may act as if they value expanded scale and scope—as proxied by revenue, for example—as well as, or instead of, profit. The enhanced valuation of increased revenue or expanded output lead the SOE to be less averse to the higher costs associated with expanded output and revenue. In aggressively pursuing expanded scale and enhanced revenues, SOEs may find it advantageous to engage in anticompetitive behavior against private, profit-maximizing enterprises.

For more than a century after the passage of the Sherman Act, the United States led the world in developing a body of legal and economic principles for analyzing anticompetitive behavior by private enterprises. The U.S. Constitution, however, is thought to immunize much of the anticompetitive behavior by SOEs from U.S. antitrust law. Within the American federalist system, the Supreme Court has long addressed whether states may impose and supervise policies that reduce competition. These cases articulate the state action immunity in U.S. antitrust law, which generously immunizes states (and, less generously, municipalities) from antitrust claims as long as they actively supervise the suppression of competition. The crude rule of thumb is that private plaintiffs suing states for anticompetitive behavior generally lose.

Far less developed is the body of law with respect to federal government activities that impair competition. If a federal SOE cloaks itself with the claim of sovereign immunity and if Congress has not consented to claims against the sovereign, including the sovereign’s economic enterprises, a plaintiff has little chance to prevail in an antitrust proceeding against the SOE. So it is not surprising that the antitrust jurisprudence on SOEs pales in comparison to American antitrust precedent on practically every conceivable business practice.

The other force that has contributed to the stunted growth of American case law on SOEs is capitalism itself. Unlike Europe, Australia, New Zealand, or even Canada, the United States has never embraced government ownership of enterprise. Railroads, telephone companies, electric utilities, banks, airlines,
steel mills, automobile factories, and aircraft plants were routinely owned and operated by the state in Europe and much of the world.\textsuperscript{7} Other than during wartime, the U.S. government generally has refrained from nationalizing and from directly managing private industries.\textsuperscript{8} (The 1927 nationalization of the radio spectrum used for wireless communications is a notable exception,\textsuperscript{9} and one that is often criticized.\textsuperscript{10})

Times have changed. The United States now feels the growing influence of the European Commission (EC) and the various national enforcement agencies around the world, as General Electric’s failed acquisition of Honeywell in 2001 attests.\textsuperscript{11} Less noticed than the defeat of the GE-Honeywell merger, but equally important for its long-term implications for the developments of competition law on all continents, was the EC’s decision in 2001 regarding Deutsche Post AG, the German postal monopoly now undergoing privatization. The EC found that Deutsche Post had used profits from its state-granted monopoly in letter mail services to subsidize efforts to dominate the parcel delivery business in Germany by pricing below cost and undercutting competitors.\textsuperscript{12} The EC ordered Deutsche Post to divest its parcel delivery business and to engage the new owner only on an arms’ length basis for any continuing commercial relationships.\textsuperscript{13}

The Deutsche Post case could soon become relevant to SOEs owned by the U.S. government. In 2002, the U.S. Court of Appeals for the Ninth Circuit held in the Flamingo Industries case that the Postal Service was subject to federal antitrust law because “Congress has withdrawn the cloak of sovereign

\textsuperscript{8} See, e.g., \textsc{Bernard M. Baruch}, \textit{American Industry in the War} 15-37 (Prentice Hall, Inc. 1941) (describing the control of U.S. industry by the War Industries Board during World War I).

\textsuperscript{10} See, e.g., Jerry A. Hausman, \textit{Valuing the Effect of Regulation on New Services in Telecommunications}, 1997 \textsc{Brookings Papers on Economic Activity: Microeconomics} 1, 43.

\textsuperscript{12} Case COMP/35.141, Deutsche Post AG, 2001 O.J. (L 125) 27 at ¶ 36 [hereinafter \textit{Deutsche Post Predatory Pricing Decision}]. Because the Europeans and many other developed economies do not use the label “antitrust,” it would be parochial to call the developing body of law on SOEs “antitrust law.” Instead, throughout this Article we shall refer to “competition law.”

\textsuperscript{13} In a related decision in 2002, the EC ordered Deutsche Post to repay to the German government the €572 million that Deutsche Post had received to finance its public service mission. \textit{See} EC press release IP/02/890 (June 19, 2002). The EC concluded that Deutsche Post had unlawfully used those funds to subsidize its pricing policy in the non-reserved parcel business.

The European Union has generally outlawed state aid within its common market. Under Article 87 of the EC Treaty, “any aid granted by a Member State or through State resources in any form whatsoever which distorts or threatens to distort competition by favoring certain undertakings or the production of certain goods shall, insofar as it affects trade between Member States, be incompatible with the common market.” Consolidated Version of the Treaty Establishing the European Community, 1997 O.J. (C 340) 173. Article 87 is generally applicable in the liberalized postal services sector. \textit{See} Notice from the Commission on the application of competition rules to the postal sector and the assessment of certain State measures to postal services, 1998 O.J. (C 39) 2, at ¶ 7(a). The underlying objective of the prohibition against state aid is to prevent trade from being affected by advantages granted by public authorities, which, in various forms, distort or threaten to distort competition by favoring certain undertakings or certain products. \textit{See, e.g.,} Case C-39/94, SFEI v. La Poste (1996), ECR I-3547, at ¶ 58.
immunity from the Postal Service and given it the status of a private corporation.”

The Ninth Circuit found that the Postal Service lost its sovereign status upon enactment of the Postal Reorganization Act of 1970, which provided: “The Postal Service shall have the . . . power to sue and be sued in its official name.”

Another significant development concerning competition law for SOEs is the complaint filed by United Parcel Service in 2000 against Canada Post under Chapter 11 of the North American Free Trade Agreement (NAFTA). Chapter 11 permits an investor of one signatory nation to initiate arbitration against another signatory nation for its failure to comply with NAFTA’s obligations concerning foreign investment and regulation of monopolies. Among other things, Chapter 11 enables a foreign firm to sue for damages caused by a nation’s preferential treatment of its SOE, even though sovereign immunity might block an analytically identical case brought by a citizen of that same nation and styled as a violation of its domestic law. The applicable law is not necessarily that of any NAFTA country.

The Flamingo Industries decision and the pending Canada Post NAFTA arbitration illustrate how American SOEs such as the U.S. Postal Service, the Tennessee Valley Authority, and Federal Prison Industries all could become the targets of analogous NAFTA complaints filed by Canadian or Mexican parties under NAFTA, as well as targets of antitrust suits filed by American plaintiffs under American law. The purpose of this Article is to begin to fill the void in the American law concerning anticompetitive behavior by SOEs. In particular, we develop a framework for identifying appropriate price floors for the products that SOEs offer in non-reserved markets, in competition with private

16. Flamingo Industries, 302 F.3d at 989 (quoting 39 U.S.C. § 401(1)).
19. Chapter 15 outlines the standards of treatment required by each signatory nation (called a “party” in NAFTA’s nomenclature) toward investors of another signatory nation. These standards include treatment of foreign investors and investments no less favorable than the better of the treatment accorded the party’s own investors and investments and the treatment accorded the investors and investments of other parties or non-parties. NAFTA, art. 1102(1)-(2), 32 I.L.M. 605, 639. Chapter 15 of NAFTA sets forth standards relating to monopolies, state enterprises, and fair competition. The chapter requires parties to ensure that any government-granted monopoly, private or public, acts in a manner consistent with NAFTA whenever the monopoly exercises any regulatory, administrative, or other governmental authority that the party has delegated to it. Id., art. 1502(3)(a), 32 I.L.M. 605, 663.
20. The governing law for such proceedings consists of NAFTA and any applicable rules of international law. Id., art. 1131(1), 32 I.L.M. 605, 645. NAFTA established the Free Trade Commission, comprised of cabinet-level representatives of each party and charged with interpreting the agreement. Id., art. 2001(2), 32 I.L.M. 605, 693. Those interpretations bind arbitration tribunals. Id., art. 1131(2), 32 I.L.M. 605, 645.
In doing so, we explain why SOEs may be more likely to engage in anticompetitive activities than are private, profit-maximizing firms.\textsuperscript{22}

We begin in Part II by examining the EC’s decision in the \textit{Deutsche Post} case. The EC correctly found that pricing below long-run average-incremental cost (LRAIC) is inappropriate for both profit-maximizing firms and SOEs. However, a higher price floor may be appropriate for SOEs. The arguments in Parts III through V explain why. Part II also reviews standard multiproduct cost concepts, including LRAIC.

Part III examines the objectives of an SOE and the prices it will set when it pursues the identified objectives and faces no pricing restriction other than the restrictions imposed by competition in non-reserved markets. We identify conditions under which an SOE will choose to set prices below marginal production costs, even though such prices generally are considered to be predatory, and thus anticompetitive.\textsuperscript{23} In addition, we discuss the methods that an SOE might employ to relax a binding prohibition against below-cost pricing. We examine an SOE’s incentives to raise the costs of existing rivals and to erect barriers to keep potential rivals from entering relevant markets. Finally, we examine the implications of an SOE’s being able to achieve cost advantages in a non-reserved market by virtue of its statutory monopoly in a reserved market. These advantages can result from economies of scope between the reserved market and the non-reserved market—economies of scope that the SOE’s rivals are denied the opportunity to achieve.

Part IV explains why SOEs may have greater ability than private firms to act anticompetitively. This enhanced ability arises in part from the expanded powers and special privileges that often are extended to SOEs. These powers and privileges can help to ensure that an SOE, unlike its private competitors, does not need to recoup the costs of its anticompetitive behavior by subsequently raising prices in non-reserved markets.

Part V presents a framework for assessing the drawbacks to using the SOE’s LRAIC as the standard for determining whether the SOE’s prices in non-reserved markets are anticompetitive. Although this standard is appropriate for evaluating allegations of predatory pricing by private firms, we argue that it

\textsuperscript{21} We refer to “non-reserved” markets rather than “competitive markets” because the latter often connotes perfectly competitive markets. Our analysis applies as well to markets characterized by imperfect competition.

\textsuperscript{22} We identify precise conditions under which an SOE will price below marginal cost, thereby extending John Lott’s important analysis. \textit{See John R. Lott, Jr., Predation by Public Enterprises, 43 J. PUB. ECON. 237 (1990). See also JOHN R. LOTT, JR., ARE PREDATORY COMMITMENTS CREDIBLE? WHO SHOULD THE COURTS BELIEVE? (Univ. Chi. Press 1999).}

We do not provide a comprehensive assessment of the benefits and costs of SOEs. In particular, we do not explain why the operation of SOEs may be preferred to operation by private, profit-maximizing firms. We also abstract from any innate cost differences between public and private enterprises, and we take as given the objective of the SOE. Therefore, this Article is not designed to deliver broad policy prescriptions regarding the proper scope of SOEs.

\textsuperscript{23} We avoid using the term “predatory pricing” to describe the behavior of SOEs. We understand that term usually to connote pricing designed to drive rivals from the market. One of our main points is that SOEs may price below cost even if doing so is certain \textit{not} to drive rivals from the market.
generally is not appropriate for SOEs. The price floor for an SOE typically should exceed the SOE’s LRAIC. The extent to which the price floor should exceed the SOE’s LRAIC depends upon a number of factors that we identify. We also explain why it is that, even though certain common benchmarks may constitute reasonable price floors in some circumstances, different price floors may be more appropriate in other circumstances. We articulate case-specific guidelines that explain the extent to which price floors should be raised above the SOE’s LRAIC.

II. THE EUROPEAN COMMISSION’S DEUTSCHE POST DECISION

The EC’s 2001 decision in the Deutsche Post case raised novel legal questions concerning the application of pricing floors to firms in network industries, including SOEs. The EC declined to apply to SOEs in network industries a lower price floor than would be applied to privately owned firms in industries that do not exhibit significant network effects. In addition, the EC clarified, for purposes of analysis of cross-subsidization or predatory pricing, the difference between a firm’s costs of supplying network capacity and its costs of supplying network usage.

A. Extending the AKZO Test to Network Industries

The established predatory pricing rule at the time of the Deutsche Post case was from a 1991 decision of the European Court of Justice, AKZO Chemie BV v. Commission. Under AKZO, a dominant firm that prices below average variable cost is presumed to have done so to eliminate its competitor and thus to have abused its dominant position. In other words, when a dominant firm has so priced its products, it is unnecessary to prove an anticompetitive intent to establish that an abuse of dominant position has occurred. This “first branch” of the AKZO test is distinct from the “second branch,” which may apply when the dominant firm prices above its average variable cost but below its average total cost.

The critical insight in the first branch of the AKZO test is that a firm that persistently fails to set a price for the single product it produces above the

24. Because we focus on the behavior of SOEs that do not seek solely to maximize profit, our rejection of LRAIC as the price floor does not conflict with the proposition that, for private firms that do maximize profit, above-cost price cuts should not be deemed predatory. See Einer Elhauge, Why Above-Cost Price Cuts to Drive Out Entrants Do Not Signal Predation or Even Market Power—and the Implications for Defining Costs, 112 YALE L.J. ___ (2002).

25. For example, as we shall explain, one “bright-line” standard that is difficult to justify on closer inspection is the SOE’s hypothetical LRAIC absent its monopoly in the reserved market.

28. Id. Because the EC had found Deutsche Post liable for predatory pricing under the first branch of the AKZO test, it did not address possible liability under the second branch. Under the AKZO’s second branch, public ownership of the dominant firm is highly relevant to anticompetitive intent. For the reasons explained in Part III, an SOE has a greater incentive to price below average total cost with anticompetitive intent than does a private firm.
average variable cost of its operations will not be financially viable. Economic rationality will prevent a profit-maximizing firm from persistently pricing below average variable cost.\(^{29}\) When prices are too low to generate profit—that is, when total costs exceed total revenues at the established prices—a firm must confront the prospect of shutting down operations. In particular, the firm should continue to operate in the short run if and only if the loss incurred when the firm stays in business (that is, total costs less total revenues) is less than the loss incurred when the firm shuts down (that is, total costs less total variable costs). Hence, the economic decision to remain in operation distills to the following simple rule: remain in operation if and only if total variable cost is less than total revenue. Because total variable cost and total revenue are both divisible by the quantity produced, the rule can be restated as: A profit-maximizing firm should remain in operation if its average variable cost of producing a product is less than the price at which it sells the product. If this condition is not met, the firm should discontinue its operations, because doing so would reduce costs by more than it would reduce revenues, and would thereby increase profit. The first branch of the *AKZO* rule captures this economic insight.

The need to articulate the *AKZO* rule more precisely for the case of a multiproduct firm was a subtlety of the *Deutsche Post* case that deserves emphasis. Strictly speaking, the EC’s recognition of the multiproduct nature of the *AKZO* test did not require breaking new legal ground, for a close reading of *AKZO* reveals that it too involved a multiproduct firm. In the original *AKZO* case before the EC in 1985, Engineering and Chemical Supplies (Epsom and Gloucester) Ltd. (ECS), a small producer of organic benzoyl peroxide in the United Kingdom, alleged that AKZO Chemie BV, part of the large multinational group AKZO, had abused its dominant position in the European Economic Community (EEC) organic peroxides market.\(^{30}\) ECS alleged that AKZO implemented “a policy of selective and below-cost price-cutting designed to damage the business of ECS and exclude it as a competitor.”\(^{31}\) ECS also claimed that AKZO’s tactics had been concentrated in a relatively specialized submarket (the flour additives sector) in the United Kingdom and Ireland, which then accounted for the majority of ECS’s sales. Such targeted behavior was allegedly intended to prevent ECS from expanding to the much broader EEC market for organic peroxides for the plastics industry. According to ECS, the actual price cutting behavior was preceded by “threatened reprisals in the flour additives sector unless ECS agreed to abandon the polymer market.”\(^{32}\)

When formulating its predatory pricing rule, the EC relied exclusively on generic cost attributes—fixed costs and variable costs—that typically apply to

31. Id. at ¶ 1.
32. Id. at ¶ 2.
firms that supply a single product. Nonetheless, the multiproduct nature of AKZO was implicit in the EC’s formulation of its pricing rule, for it observed: “Besides being one of several facilities in the EEC where AKZO produces organic peroxides for the polymer industry, AKZO UK also manufactures benzoil peroxide compounds for use as a bleaching agent in the commercial baking of bread together with other associated flour or milling additives.” Consequently, the EC’s task in Deutsche Post of explaining the application of AKZO to a multiproduct firm in a network industry was more a challenge of economic explication than of doctrinal legal analysis.

The EC concluded that the appropriate multiproduct counterpart to variable cost is long-run average incremental cost (LRAIC). To help understand this conclusion and its implications, a brief review of this and other standard multiproduct cost concepts is provided next.

B. Cost Definitions

Most of the cost concepts discussed here have acquired clear meanings in economic theory and regulatory practice. The distinction between capacity costs and usage costs, however, is less well understood. It therefore deserves clarification, particularly in light of its relevance to network industries in which multiproduct SOEs often operate.

Incremental cost is a generic concept that refers to the increase in the firm’s total cost when it expands its output of a particular product or products by some specified increment, holding constant the amount of other products that the firm produces. Often, the increment in question is the entire output of the relevant product. Average incremental cost is incremental cost per unit of the output in question. Marginal cost generally differs from average incremental cost. The marginal cost of product X refers to the increase in the firm’s total outlays that result from a small increase in the output of X. Marginal cost can be approximated by average incremental cost if the increment in question is small. But if the increment is large, marginal cost and average incremental cost can differ substantially.

---

33. The EC observed that “AKZO . . . argues that the only criterion for assessing the legality or otherwise of its conduct is whether the prices it charged were above its average variable costs (used as a proxy for marginal costs).” Id. at ¶ 75. The EC said that a finding that AKZO’s prices were indeed “above ‘variable’ or ‘marginal’ cost depends upon accepting at face value AKZO’s classification of costs which treats as ‘variable’ only raw material and energy costs.” Id. at ¶¶ 75-76. The EC later defined variable costs as those that vary depending on the quantities produced, such as “materials, energy, direct labour, supervision, repair and maintenance, and royalties,” and it defined fixed costs as those that remain constant regardless of the quantities produced, such as “management overheads, depreciation, interest and property taxes.” Id. at ¶ 58.

34. Id. at ¶ 5.

35. Even before the Deutsche Post decision, the EC had accepted the applicability of the AKZO test to the provision of telecommunications services, for which regulators have examined estimates of average-incremental cost for many years. COMMUNICATION FROM THE COMMISSION ON THE APPLICATION OF THE COMPETITION RULES TO ACCESS AGREEMENTS IN THE TELECOMMUNICATIONS SECTOR—FRAMEWORK, RELEVANT MARKETS AND PRINCIPLES, 1997 O.J. (C 76) 9.

The incremental cost of product \( X \) is computed by taking the difference between (1) the total cost of the firm if it were to produce all of its products and (2) the total cost of the firm if it were to produce all of its products except product \( X \). This difference in the firm’s total costs is the incremental cost of producing \( X \). If the resulting incremental cost measure is divided by the number of units of product \( X \) that the firm produces, then the result will be an average, or per-unit, estimate of that product’s incremental cost—namely, the average-incremental cost of \( X \), or AIC\(_X\). Although such calculations are relatively fact-intensive, they are routinely generated for regulatory proceedings in telecommunications, energy, and other network industries.

The concepts of average-incremental cost and average-variable cost are closely related. However, there are differences in their common interpretations. First, average-variable cost generally is used in the simple case where a firm produces a single product. Second, average-variable cost sometimes is used to refer to short-run cost, where capacity is not adjusted to output volume. In contrast, average-incremental cost generally is the long-run figure obtained after plant and equipment are adjusted so as to minimize the average cost of the pertinent output. It is therefore often called long-run average-incremental cost. Third, the average-incremental cost of \( X \) includes any fixed cost that must be incurred to produce that product alone.\(^{37}\) A key difference between the average-variable cost and the average-incremental cost of product \( X \) is that the latter explicitly includes all fixed costs attributable to only product \( X \). A price floor equal to the average-incremental cost of product \( X \) would require the producer to recover in its revenue from the sale of \( X \) both the fixed costs and the variable costs attributable only to product \( X \).

The stand-alone cost of service \( X \) (SAC\(_X\)) is the outlay that would be required for a firm to produce service \( X \) and no other service. The concept of stand-alone cost also applies to combinations of services or products. The stand-alone cost of products \( Y \) and \( Z \) (SAC\(_{Y,Z}\)), for example, is the cost incurred by a firm producing only products \( Y \) and \( Z \). Stand-alone cost differs from incremental cost in part because the stand-alone cost of producing multiple products can include costs that are common to the group of products in question, even if the costs are not incremental to the production of any one of the products individually.

A cross-subsidy is present when the extra revenue derived from the sale of a product of a firm is less than the incremental cost of the product, but the firm nevertheless earns sufficient revenue from all its products to cover all of its costs. When total revenue exceeds total cost, some products other than the cross-subsidized product must be generating the revenue required to offset the shortfall of the revenues of the cross-subsidized product. Thus, one can say that product \( X \) receives a subsidy if its revenues are inadequate to cover the costs caused by the firm’s supply of \( X \), but the firm’s overall operations are financially viable.

As noted above, average-incremental cost includes any fixed cost incurred exclusively for the service in question. But the average-incremental cost of service \( X \) does not include any contribution toward any fixed costs incurred in

\(^{37}\) See id. at 57-58.
common for X and some other service Y supplied by the same firm. In this simple two-product example, a particular common cost constitutes no part of the incremental cost of either X or Y by itself. But it is distinctly included in the incremental cost of X and Y in combination. Thus, to ensure economic efficiency in this example, the following three conditions must all be satisfied: (1) the price of X must not be below the AIC of X; (2) the price of Y must not be below the AIC of Y; and (3) the prices of X and Y must be such that their combined incremental revenue is not less than the combined incremental cost of X and Y together. This case is the simplest version of the combinatorial incremental-cost test, introduced by Gerald Faulhaber.38 A profit-maximizing firm will set prices that satisfy the combinatorial incremental-cost test. If it did not, the firm could increase its profits by setting different prices. The more general version of the combinatorial test states that the prices of the firm must be such that the resulting revenue of every product by itself, and the combined revenue of every combination of the firm’s products, must at least equal the corresponding average-incremental costs of production.

The proper implementation of the combinatorial incremental cost test can help to avoid erroneous conclusions about appropriate price floors. To illustrate this point, suppose a firm produces three products, X, Y, and Z. Suppose further that when it is producing Z, the firm’s incremental cost of producing X and Y is relatively high, but its incremental cost of X is low and its incremental cost of Y is also low. In this case, if price floors simply reflected product-specific incremental costs, the appropriate price floors for X and Y would both be low. However, if prices were set at these (low) floors, the firm’s incremental revenue from X and Y would fall short of the incremental cost of producing X and Y. Under such circumstances, higher price floors for X and/or Y would be appropriate to ensure that the firm does not drive a more efficient supplier of goods X and Y from the market.

Prices that are set at or above product-specific average incremental-costs and that satisfy the combinatorial incremental-cost test preclude cross-subsidies. This is the case because a product or group of products is being cross-subsidized only if it generates incremental revenue below the relevant incremental cost of production.

This review of cost concepts makes it clear that the EC correctly interpreted LRAIC as the appropriate multiproduct counterpart to variable cost in Deutsche Post. We now proceed to review the details of the EC’s Deutsche Post decision.

C. The Deutsche Post Decision

Deutsche Post AG (DPAG) is a public limited company that in 1995 succeeded to Deutsche Bundespost Postdienst, which was a section of a special federal fund. Deutsche Post functions much like the U.S. Postal Service and has

a profitable letter mail monopoly in Germany. Deutsche Post also has a business parcel delivery operation that faces competition from United Parcel Service (UPS), Federal Express, and others. Deutsche Post’s expansion from monopoly letter mail services into non-reserved parcel delivery services raises the issue not of a competitors’ access to services controlled by Deutsche Post, but rather the use of infrastructure and cash flows available to Deutsche Post as a regulated public monopoly to distort competition in an adjacent market.

In the early 1990s, UPS complained to the EC that Deutsche Post was using letter mail monopoly profits to subsidize the sale of its parcel delivery services at below-cost prices. In July 1994, UPS asked the EC to stop the allegedly predatory pricing and to separate Deutsche Post’s letter mail business from its parcel delivery businesses. In March 2001, the EC found that for five years Deutsche Post failed to cover incremental costs in its pricing of parcel delivery service, violating Article 82 of the EC Treaty.

1. Cross-subsidization in Non-reserved Markets

The EC concluded that Deutsche Post’s overall revenues in the reserved area (letter mail) exceeded its stand-alone costs, whereas revenue from its mail-order parcel service was below the incremental cost of providing that specific service. Such mail-order parcels are not processed through the postal counter system but are collected by Deutsche Post directly at the customers’ premises. After collecting these parcels, Deutsche Post used the same infrastructure to process mail-order services that it used to process other commercial parcel services. These other commercial parcel services are business-to-business parcels (B-to-B), parcels that are handed in at post office counters and sent from one private person to another (P-to-P-services), and mail-order returns (P-to-B-services). During the years of the EC investigation, mail-order services accounted for approximately 71 percent of the total volume of all commercial postal services.

The EC defined cross-subsidization to occur when “the earnings from a given service do not suffice to cover the incremental cost of providing that service and where there is another service or bundle of services the earnings from which exceed the stand-alone cost.” Consequently, the EC stated that “when establishing whether the incremental costs incurred in providing mail-order parcel services are covered, the additional cost of producing that service,

40. Deutsche Post Predatory Pricing Decision, supra note 12, at ¶ 36. The EC also found that Deutsche Post had violated Article 82 by granting “fidelity rebates” to large customers. Id. at ¶ 33, 37. For this violation, the EC fined Deutsche Post €24 million. Id. at ¶ 51.

incurred solely as a result of providing the service, must be distinguished from the common fixed costs, which are not incurred solely as a result of this service.\textsuperscript{46} In making that incremental calculation, the EC considered the impact of Deutsche Post’s universal-service obligation.

2. \textit{Universal Service and the Appropriate Price Floor}

The presence of a universal service obligation (USO) can affect significantly a firm’s incremental costs of production. To understand why, consider, first, the example of an independent, profit-maximizing barge owner who faces no obligation to provide service. Such an entrepreneur can design the barge’s capacity however he likes, even if he is a dominant supplier. He can incur the fixed costs of constructing an enormous barge that is capable of accommodating the shipments of the highest-volume shippers. If he does so, he will need to forecast the likely demand of such shippers, and then he will bear the risk (or will need to contract around the risk) that his enormous barge will sometimes leave him with excess capacity. Alternatively, the barge owner may incur lower fixed costs to build a smaller barge, which will have a higher likelihood of operating at full capacity. If the barge owner faces excess demand with the smaller barge, he can raise his price and thus ration the scarce capacity of his barge to those customers who value the service at least as highly as the specified price.

Now, in contrast, consider how an SOE like Deutsche Post might determine the characteristics of its delivery network. The government has announced a social policy of universal access, geographically averaged prices, and minimum service-quality standards. That policy implies for the SOE a particular capacity requirement for its letter delivery network, as well as an “obligation to serve” all customers as the “carrier of last resort.”\textsuperscript{47} Once the SOE has built its delivery network according to these mandates, its “barge” must sail every specified day, regardless of whether it is nearly empty or entirely full. Unlike the owner of a real barge who bears no obligation to serve, the SOE may not raise prices (or offer particular customers inferior service quality) to ration scarce capacity on its delivery network when faced with excess demand. Similarly, a firm with a USO does not lawfully have the discretion to limit its output by restraining the capacity of its network. The firm’s USO generally compels it to supply a level of network capacity that exceeds the level of network capacity that would be supplied in a competitive market by firms that do not have USOs. “Mandating that the [regulated incumbent firm] alone act as the carrier of last resort forces the firm to hold capacity in reserve to meet demand at peak load.”\textsuperscript{48} The SOE must therefore build its network with “reserve” or “standby” capacity that will accommodate peak demand.

\textsuperscript{46} \textit{Id.} at ¶ 7.

\textsuperscript{47} For economic analysis of the obligation to serve, see J. GREGORY SIDAK & DANIEL F. SPUBLER, DEREGRULATORY TAKINGS AND THE REGULATORY CONTRACT: THE COMPETITIVE TRANSFORMATION OF NETWORK INDUSTRIES IN THE UNITED STATES 119-29 (Cambridge University Press 1997).

\textsuperscript{48} \textit{Id.} at 513.
To provide customers the option of sending letters on any given day to any given destination in the nation, the SOE must incur many kinds of costs that do not vary with the number of letters ultimately transported that day. One cannot attribute such network costs to any particular customer. The cost of standing ready to provide service on demand cannot be attributed to Customer A rather than Customers B and C, because the firm is required to offer the same service to all of them. Consequently, “when a regulated firm has special-service obligations imposed upon it,” “[t]hese obligations are appropriately treated as sources of common fixed costs for the firm . . . .”49 The SOE’s USO implicitly requires it simultaneously to offer both network access and network usage. Even if a customer sends no letters on a given day, he will nonetheless have had enjoyed the option to do so.50 The delivery infrastructure was there to be used, if the customer had wanted to use it.

The option value of network access has implications for network capacity and for the distinction between network capacity costs and network usage costs. To ensure that consumers will be able to use the delivery network with relative ease, if they so desire, the network must be designed with capacity sufficient to accommodate expected demand, including peak demand during particular times of the day, month, or year. Such capacity costs are, by definition, fixed—they have already been made when a customer ships a parcel. Stated differently, if an existing customer stopped using the SOE’s delivery network, these fixed costs of network capacity could not be avoided. The fixed costs of the network neither increase nor decrease when a particular customer, large or small, actually uses the network for parcel delivery service. Such fixed costs may include labor as well as capital.

The distinction between network capacity costs and network usage costs is intimately related to the scale of the network required to ensure a reasonable quality level for core operations. Absent strategic behavior, it would seem reasonable to count as overhead costs all costs associated with the network infrastructure required to ensure the established level of core service quality, even if they also support the delivery of non-core services. However, such a classification provides strong incentives for the SOE that wishes to expand the scale and scope of its operations to set too high a quality standard for its core services, because a high quality standard can justify expanded network investment (to ensure ample reserve capacity, for example), which can lower the SOE’s incremental cost of providing non-core services.

Under the German Postal Universal Service Ordinance, Deutsche Post must maintain a capacity reserve large enough to cover any peak demands that may arise in over-the-counter parcel services while meeting statutory service-quality

49. BAUMOL & SIDAK, supra note 36, at 108-09.
50. The analogous option value inherent in the telecommunications network is well recognized. See, e.g., J. Gregory Sidak & Daniel F. Spulber, Cyberjam: The Law and Economics of Internet Congestion of the Telephone Network, 21 Harv. J.L. & Pub. Pol’y 337, 362 (1998) (“There are costs associated with providing both connections and standby capacity to supply the option to achieve a connection. The costs of standby capacity are capital costs of network capacity that are similar to the merchant’s cost of holding inventory to provide ‘immediacy’ to customers.”).
standards for those services.\textsuperscript{51} Parcel services up to a weight of 20 kilograms are included in Deutsche Post’s USO.\textsuperscript{52} At least 80 percent of the parcels covered by the universal-service obligation must be delivered within two business days (known as D+2).\textsuperscript{53} To comply with universal-service obligations, Deutsche Post must also maintain a certain minimum number of facilities, including at least one in every city with more than 2,000 inhabitants.\textsuperscript{54}

As a consequence of these obligations, the EC concluded that even “if Deutsche Post were to stop offering a specific parcel service, it could not, unlike a private firm like UPS, cut back on staff and equipment in perfect proportion to the reduction in volume,” because “some staff and equipment are also needed to provide over-the-counter-services that meet statutory quality standards.”\textsuperscript{55} Therefore, the EC held that “the costs of maintaining capacity arise independently of the services provided and the volume of parcels processed only as a consequence of maintaining capacity to allow everyone the standard option of having their parcels sent over-the-counter the normal way.”\textsuperscript{56}

These capacity costs consequently were found not to be attributable to a specific service, but rather to constitute common fixed costs.\textsuperscript{57} Only where services other than over-the-counter parcel services are provided can costs be attributable to a specific service. Such costs cease to exist if the service at issue is stopped. The EC held that, to avoid subsidizing mail-order parcel services, Deutsche Post must earn revenue from this parcel service that at least covers the cost attributable (incremental) to producing the specific service, but not revenue sufficient to cover the network capacity costs that the SOE incurs as a result of its statutory USO.\textsuperscript{58}

To determine the particular incremental costs of providing mail-order parcel services, the EC examined every stage in mail-order parcel processing (collection, sorting, long-distance transport, regional and local transport, and delivery) and asked whether these costs would be saved if mail-order services were discontinued. The EC concluded that all the costs of collection were fully attributable to the mail-order service because the parcels (unlike over-counter-services) are collected by Deutsche Post from the customer’s premises and transported directly to one of the 33 outward and inward freight centers.\textsuperscript{59}

Regarding sorting, the EC found that capital cost of creating freight centers and delivery points could not be attributed to a particular service because these costs would be incurred as long as the USO for over-the-counter parcels applies to the postal service, whereas staffing and equipment cost of sorting depend entirely on traffic volume and can be attributed in direct proportion to the mail-

\end{itemize}
order services. Costs of long-distance transport, in terms of staffing, equipment, and capital, were not attributed to a particular service, because they could only be eliminated if universal-service obligations no longer applied to parcel services. Costs of regional and local transport (between freight centers and delivery points) were attributed 50 percent to mail-order services. Finally, delivery costs were divided into the cost of driving, which is not attributable to a specific service, and the cost of stopping and handing over the parcel, which is partially attributable to mail-order services.

On the basis of this distribution between common costs and product-specific costs, the EC concluded that revenue generated from mail-order services did not suffice to recoup product-specific costs. Consequently, during the relevant period at issue in the case, every additional sale of mail-order services not only entailed the loss of at least part of the services’ cost, but also made no contribution toward Deutsche Post’s capacity maintenance costs. By “remaining in the market without any foreseeable improvement in revenue,” Deutsche Post was found to have “restricted the activities of competitors, which are in a position to offer the service at a price that covers their cost.”

3. Remedy

In ordering a remedy for this violation of Article 82, the EC sought to “guarantee that competitors are not eliminated by offers which are not based on efficiency or superior performance, but solely on a basis of a price below the additional costs of providing the competitive service.” Deutsche Post was required to structurally separate its reserved letter mail business from its parcel delivery business, the latter to become a separate legal entity operating under a new name. This new firm—Deutsche Post Euro Express—may procure necessary inputs (such as sorting, transport, and delivery) by purchasing them from Deutsche Post or its competitors, or by producing the inputs itself. If the new entity chooses to purchase inputs from Deutsche Post, Deutsche Post must provide them at market prices. In addition, all input services supplied by Deutsche Post to the new entity must be supplied to its competitors at the same price and on the same conditions. The EC intended that, with these structural and behavioral rules in place, Deutsche Post would have no incentive to treat the new firm differently from other parcel delivery services—in particular, to sell inputs to the affiliated firm at prices below incremental cost.

III. WHY STATE-OWNED ENTERPRISES MAY HAVE STRONGER INCENTIVES THAN PRIVATE FIRMS TO ACT ANTICOMPETITIVELY

The EC’s conclusion that Deutsche Post should not be permitted to set prices below LRAIC is undoubtedly correct. A question remains, though, as to whether SOEs should be required to set prices significantly above LRAIC in non-reserved markets. For the reasons presented in this Part and the next, we believe a price floor above LRAIC generally is appropriate for SOEs.

In this Part, we explain why SOEs may have stronger incentives than private firms to engage in anticompetitive activities. We demonstrate that when an SOE values an expanded scale of operation in addition to profit, it will be less concerned than its private, profit-maximizing counterpart with the extra costs associated with increased output. Consequently, even though an SOE may value the profit that its anticompetitive activities can generate less highly than does a private profit-maximizing firm, the SOE may still find it optimal to pursue particularly aggressively anticompetitive activities that expand its own output and revenue. To illustrate, the SOE might set the price it charges for a product below its marginal cost of production, particularly if the product is one for which demand increases substantially as price declines. If prohibitions on below-cost pricing are in effect, an SOE may have a strong incentive to understate its marginal cost of production or to over-invest in fixed operating costs so as to reduce variable operating costs. A public enterprise may also often have stronger incentives than a private, profit-maximizing firm to raise its rivals’ cost and to undertake activities designed to exclude competitors from the market because these activities can expand the scale and scope of the SOE’s operations.

A. The Objective of an SOE

Different SOEs often have different assigned missions and different goals. For example, the U.S. Postal Service is charged with providing ubiquitous service throughout the United States at uniform rates across different geographic regions. Congress has mandated:

The Postal Service shall have as its basic function the obligation to provide postal services to bind the Nation together through the personal, educational, literary, and business correspondence of the people. It shall provide prompt, reliable, and efficient services to patrons in all areas and shall render postal services to all communities. The Postal Service shall provide a maximum degree of effective and regular postal services to rural areas, communities, and small towns where post offices are not self-sustaining.69

When it proposes rate increases (subject to Postal Rate Commission review), the Postal Service is required to consider the fairness, equity, and simplicity of its rate structure (across multiple services) as well as the relationships among prices, production costs, and the value of the service provided.70 Such mandates

70. Id. at § 3622.
indicate that, in contrast to the typical private firm in a capitalist society, SOEs seldom seek solely to maximize the profit they generate. The profit that SOEs are permitted to earn often is explicitly limited, and SOEs are commonly instructed to pursue goals that are distinct from, if not fundamentally incompatible with, profit maximization.\(^{71}\)

In practice, an SOE is not a monolithic entity that faithfully executes its mandate. Rather, it is an organization comprised of many individuals, including managers who often have considerable discretion to pursue their own objectives. This discretion arises in part because SOEs are not subject to takeover threats and are generally less subject to the discipline of capital markets than are private enterprises. Even though the managers of private, profit-maximizing firms may have goals and interests similar to those of managers in SOEs, the discipline of capital markets will limit the freedom of private managers to pursue private interests that do not maximize shareholder value.\(^{72}\) Managers of SOEs (and government officials who monitor them) often have considerable interest in expanding the scale or scope of their activities, in part because a manager’s abilities may be inferred from the size of the operations that he or she oversees.\(^{73}\)

This preference for expanded scale and scope of operations suggests that SOEs might act as if they seek to maximize some combination of profit and a measure of operating scale.\(^{74}\) In practice, revenue often serves as a convenient proxy for scale, because revenue provides a natural metric for comparing the outputs of multiple products.\(^{75}\) Thus, one might view the SOE as seeking to

---

\(^{72}\) See William Niskanen, Bureaucracy and Representative Government (Aldine-Atherton 1971). See also William Niskanen, Bureaucrats and Politicians, 18 J.L. & Econ. 617 (1975). In summarizing the relevant empirical evidence, Andre Blais & Stephane Dion, Conclusion: Are Bureaucrats Budget Maximizers, in The Budget-Maximizing Bureaucrat: Appraisals and Evidence 355 (U. Pitt. Press 1991) conclude that bureaucrats may seek to expand the scale of their operations (by securing larger budgets) to realize the power and prestige that often accompany expanded operations. Expanded output can also promote expanded employment, which can be a goal of SOEs.

\(^{75}\) William Baumol has observed: “In ordinary business parlance the term ‘sales’ refers not to the number of physical units . . . but, rather, to the total revenue obtained by the firm from the purchases of its customers.” William J. Baumol, Business Behavior, Value and Growth 32 (MacMillan Co. 1959) (emphasis added). Furthermore, “in the near universal multi-product firm any measure of overall physical volume must involve index number problems, and the adoption of a value measure is doubtless to be expected.” Id. at 45.
maximize a weighted average of revenue and profit. Different SOEs may value these two performance dimensions differently. To capture differences among SOEs, we employ the parameter $w$, which can range from 0 to 1, to denote the weight that an SOE places on revenue. We will also let $1 - w$ denote the corresponding weight on profit. By varying $w$, we can capture the objectives of different SOEs.

In the discussion that follows, we focus on this simple class of objective functions for the SOE. However, it is important to note that the key qualitative conclusions drawn in this discussion hold more generally. The conclusions hold, for example, if the SOE seeks to maximize a weighted average of output and profit, or if it seeks to maximize revenue (or output) subject to the constraint that its profit exceed some specified level. The key assumption is that the SOE values revenue or output as well as profit. Its concern with revenue or output effectively induces the SOE to discount the cost of output expansion. Consequently, even though the SOE values the profit that its anticompetitive activities can generate less highly than does a private profit-maximizing firm, the SOE finds it optimal to pursue particularly aggressively anticompetitive activities that serve to expand its own output and revenue. In essence, the SOE’s increased concern with output outweighs its reduced concern with profit in determining its interactions with competitors.

Before proceeding, it is convenient to introduce a formal statement of the class of objective functions under consideration. The formal statement employs the following simple notation. Let $n \geq 1$ denote the number of products supplied by the SOE. Also let $p_i \geq 0$ denote the price that the SOE charges for its $i$-th product, and let $p = (p_1, \ldots, p_n)$ denote the prices the SOE charges for its $n$ products. In addition, let $Q_i(p)$ denote the amount of product $i$ that customers will buy when the SOE sets prices $p$. (Customers will buy more of any product the lower is its price.) $Q = (Q_1(p), \ldots, Q_n(p))$ will denote all of the output produced by the SOE. For simplicity, the ensuing discussion will focus on the setting in which customer demand for each of the SOE’s products is independent of the prices charged for other products. Unless otherwise noted, the discussion will also abstract from cost complementarities by assuming that the SOE’s cost of supplying one product does not vary according to the amount

76. Alternative objective functions for SOEs are certainly possible, and some are discussed below. For example, managers of SOEs may seek to maximize those dimensions of output that are most highly valued by and most readily monitored by Congress, subject to specified budget constraints. See Cotton Lindsay, *A Theory of Government Enterprise*, 84 J. POL. ECON. 1067 (1976). For simplicity, we abstract from multiple performance dimensions, although this possibility merits attention in future research.

77. This is not to say that all of the qualitative conclusions drawn below necessarily hold whenever an SOE is not concerned solely with profit maximization. Suppose, for example, that an SOE seeks to maximize the sum of consumer and producer surplus. Suppose, for example, that an SOE seeks to maximize the sum of consumer and producer surplus. In this case, even though the SOE will typically expand output beyond profit-maximizing levels, it will not generally set prices below marginal production costs. Although the objective of welfare maximization merits further consideration, the objective abstracts from a range of management and control issues within public firms.
of the other products it supplies. The function $C(Q)$ will denote the SOE’s cost of producing output $Q$.\footnote{In this simple setting with independent demands, $\partial Q_i(p)/\partial p_j = 0$ for all $j \neq i$, and so the demand for the SOE’s $i$-th product can be written as $Q_i(p)$. Furthermore, in the absence of cost complementarities, the SOE’s cost function can be expressed as $C(Q) = \sum_{i=1}^{n} C_i(Q_i(p_i))$.}

This notation enables us to specify the SOE’s objective, which is to maximize:

$$w \left[ \sum_{i=1}^{n} p_i Q_i(p) \right] + \left[ 1 - w \right] \left[ \sum_{i=1}^{n} p_i Q_i(p) - C(Q) \right].$$

(1)

The first term in square brackets in expression (1) is the SOE’s total revenue. Total revenue is the sum of the revenue derived from the sale of each of the SOE’s $n$ products. The revenue derived from the sale of any particular product ($i$) is simply the product of the number of units of the product sold ($Q_i$) and the price ($p_i$) at which each unit is sold. The last term in square brackets in expression (1) is the SOE’s profit. Profit is the difference between total revenue and total operating cost. Thus, with the weight $w$ applied to revenue and the weight $[1 - w]$ applied to profit, expression (1) is simply the aforementioned weighted average of revenue and profit.

**B. An SOE’s Pricing**

Before discussing the prices preferred by an SOE that seeks to maximize a weighted average of revenue and profit, we consider the prices that a private, profit-maximizing firm would set in the simple, static setting described above. It is well known that a firm will maximize profit in this setting by raising prices above marginal production costs by amounts that are inversely proportional to the sensitivity of customer demand to price.\footnote{See Frank Ramsey, *A Contribution to the Theory of Taxation*, 37 ECON. J. 47 (1927); William J. Baumol & David F. Bradford, *Optimal Departures From Marginal Cost Pricing*, 60 AM. ECON. REV. 265 (1970).} In other words, the firm will set the price for a product close to its marginal cost of production when a higher price would cause many potential customers to decide not to purchase the product. In contrast, on products for which customer purchases do not decline much in response to price increases, the profit-maximizing firm will set prices well above marginal production costs.

This pricing strategy is summarized formally in Finding 1. The Finding refers to $\varepsilon_i = |\partial Q_i(p)/\partial p_i| |p_i/Q_i|$, which is the own-price elasticity of demand for product $i$. The price elasticity of demand for product $i$ measures the rate at which customer purchases decline as the price of product $i$ increases. The larger is the price elasticity of demand for a product, the more pronounced is the decline in customer purchases as the price of the product increases.

*Finding 1*. The preferred prices of a profit-maximizing multiproduct firm are characterized by the following inverse-elasticity rule:
Expression (2) indicates that the profit-maximizing firm will always set the price of each of its products above its marginal cost of production. In the simple, static setting considered here, reducing a price below marginal cost serves only to reduce profit, and so such pricing is not attractive to the profit-maximizing firm.

Now consider the prices preferred by a multiproduct SOE that seeks to maximize a weighted average of revenue and profit in the same setting. The prices that maximize expression (1) are characterized in Finding 2.

Finding 2. The SOE’s preferred prices are characterized by the following modified inverse-elasticity rule:

$$\frac{p_i - \frac{\partial C_i(Q)}{\partial Q_i}}{p_i} = \frac{1}{\varepsilon_i}, \quad \text{for } i = 1, \ldots, n. \tag{3}$$

Finding 2 reveals that the prices preferred by an SOE that seeks to maximize a weighted average of revenue and profit in the same setting follow a modified inverse-elasticity rule. To maximize a weighted average of revenue and profit, the SOE implements proportional markups of price over modified marginal cost, \([1 - w]\frac{\partial C(Q)}{\partial Q}\), that vary inversely with the price elasticity of demand. Prices are set further above modified marginal cost the more inelastic is the demand for the product.

Expressions (2) and (3) reveal that the SOE’s pricing rule is the same rule that a profit-maximizing firm follows, except that marginal costs are scaled down by the factor \(1 - w\) to reflect the SOE’s reduced focus on profit. The greater is its focus on revenue rather than profit (that is, the larger is \(w\)), the more the SOE discounts marginal costs in the modified inverse-elasticity rule.

This discounting of marginal costs reflects the fact that, as the SOE becomes more concerned with revenue relative to profit, it becomes less averse to the higher costs that arise from increased output. Consequently, the SOE favors more highly the expanded output and revenue that result from low prices on those products for which competition from alternative suppliers is most pronounced. The rule suggests that when such competition exists, a reduced focus on profit may lead the SOE to set particularly low prices for the products on which it faces the most intense competition. This conclusion supports John

---

80. This conclusion follows because the price elasticity of demand is always a positive number. Therefore, the term to the right of the equal sign in expression (2) is positive, which implies that the expression to the left of the equal sign must also be positive. This latter expression will be positive only if price \(p_i\) exceeds marginal cost \(\frac{\partial C_i(Q)}{\partial Q_i}\).

81. This fact may be seen most readily by noting that expression (1) can be written as the difference between revenue and modified cost, where modified cost is total cost scaled by the factor \([1 - w]\).
Lott’s observation that an SOE might set the price of a product below its marginal cost of production.82

Conclusion 1. Even in the absence of predatory intent, a SOE may set the prices for some of its products below their marginal costs of production. The SOE may be particularly likely to prefer below-cost prices when its focus on profit is more limited and when customer demand for its products are more sensitive to price.

Conclusion 1 holds because, even though profit declines as the SOE reduces price below marginal cost, revenue can increase as price declines. Therefore, if the SOE’s relative valuation of revenue is sufficiently pronounced or if customer demand for some of its products is sufficiently sensitive to price (or both), then the SOE may choose to set some prices below marginal production costs even when demands are independent. In doing so, the SOE may drive a more efficient competitor from the market.

C. Avoiding Restrictions on Below-Cost Pricing

The foregoing analysis considers the prices preferred by an SOE when its pricing flexibility is unrestricted. In practice, an SOE may face restrictions on feasible prices. For example, an SOE might be prohibited from pricing below marginal cost, just as private, profit-maximizing firms typically are. We now explain how firms might attempt to relax a binding prohibition against below-cost pricing, and why a public enterprise can have stronger incentives than a profit-maximizing firm to relax such a prohibition.

One obvious way in which a firm might attempt to relax a binding constraint against pricing below marginal cost is to manipulate accounting data so as to understate its actual marginal cost.83 Such understatement might be achieved by classifying, as overhead production costs, some or all of the costs that truly vary as output varies. For example, the firm might count some of the personnel hired to supply the product in question as central management. An alternate way for the firm to understate its true marginal cost is to record, as variable costs incurred in the provision of a different product, costs that are truly incurred in producing the product whose price the firm would like to set below marginal cost. For example, the firm might claim that materials and supplies employed to produce the product in question were employed to produce a different product.

Intentional understatement of marginal production costs is likely to entail personal risk. Laws against fraud carry severe financial penalties, and career prospects can be dimmed for managers who are suspected of knowingly reporting false information. But even if the SOE bears the full costs of the manipulation (and thus does not discount those costs by the factor 1 – w, as it

82. Lott, supra note 22, at 237.
implicitly discounts production costs), the associated benefits may outweigh the costs. Most importantly, when the SOE values more highly the expanded output and revenue that result from the lower price that the understatement facilitates than does a private, profit-maximizing firm, the SOE will be more likely than its private counterpart to understate its costs.84 For emphasis, we record this observation formally as Conclusion 2.

Conclusion 2. An SOE will often have substantial incentive to understate its marginal cost of production to relax a binding prohibition against pricing below cost. The less profit-oriented is the SOE, the greater this incentive can be.

Now consider a more subtle strategy that an SOE might pursue to relax a binding prohibition against pricing below cost. Suppose that instead of misstating its true marginal cost, the SOE chooses to operate with an inefficient technology that secures a relatively low marginal cost at the expense of a particularly high overhead cost. In practice, a firm might do so by installing general-purpose equipment on a large scale and thereby reduce the need for project-specific equipment. It might also do so by, for example, retaining a large on-site staff with broad legal, engineering, computing, and/or marketing expertise that can substitute for specific expertise on individual products.

More generally, suppose that the SOE has a choice among production technologies and suppose that this choice is indexed by the amount of an overhead resource that the firm employs. For expositional convenience, refer to this resource as “capital.”85 The more capital the firm installs, the lower are its variable and marginal costs of production. In this setting, the following conclusion is readily verified.

Conclusion 3. An SOE will often have a strong incentive to overinvest in capital to relax a binding prohibition on pricing below cost. The less profit-oriented is the SOE, the greater this incentive can be.

The more highly the SOE values expanded scale and scope relative to profit, the more it benefits from the expanded scale that a lower price provides and the less concerned it is with the associated cost. Therefore, the less concerned that the SOE is with generating profit, the greater the technological inefficiency it may endure to secure a lower price and the expanded scale it engenders. Conclusion 3 reports that the SOE may install an inefficiently large level of capital to reduce its marginal cost even if it faces the same market cost of capital that private enterprises face. If the SOE’s capital purchases are subsidized (as they can be, for example, if the SOE is afforded privileged access to government funds), then inefficient over-capitalization can become even more pronounced.

84. In the simple setting considered here, a profit-maximizing firm will set price above marginal cost and will not understate marginal cost. In a dynamic setting with entry barriers, however, a profit-maximizing firm might choose to price below marginal cost and understate marginal cost.

85. The overhead cost could include labor. The critical feature of overhead cost is that it does not vary with the level of output produced by the firm.
For simplicity, the ensuing discussion focuses on the case where the cost of producing each product is independent of the cost of producing other products. The presence of cost complementarities, though, can provide an SOE with an additional means to relax a binding prohibition on pricing below cost. To illustrate this point, suppose the SOE produces two products, A and B. Further suppose the SOE is, by law, the sole supplier of product A, whereas the SOE and competitors both supply product B. Finally, suppose there are economies of scope in the provision of products A and B that cause the SOE’s marginal cost of producing B to decline as the SOE’s supply of product A increases. In the presence of such cost complementarities, the SOE can secure a lower marginal cost for product B by increasing its output of product A. This output expansion might be accomplished, for example, by agreeing to take on an expanded universal service obligation in the delivery of product A. Consequently, when cost complementarities are present, an SOE can gain in two distinct ways from accepting an expanded universal service obligation. First, it can increase the scale and scope of the SOE’s monopoly operations. Second, it can reduce the SOE’s cost of supplying product B. This reduction in marginal cost can serve to expand the SOE’s production of product B quite generally. It can be of particular value in this regard when the SOE faces a binding restriction on pricing below cost.

In sum, an SOE’s preference for expanded scale and scope may leave it with particularly strong incentives to disadvantage competitors by strategically relaxing a binding prohibition against below-cost pricing in a variety of ways.

D. Raising Rivals’ Costs

To disadvantage their rivals, firms might undertake activities other than strategically relaxing a binding prohibition against below-cost pricing. For example, firms might lobby for regulations that increase rivals’ operating costs, restrict rivals’ access to essential productive inputs, and buy excessive amounts of inputs to raise the market price of these inputs.86

The preceding discussion suggests why a public enterprise may have particularly strong incentives to raise the costs of its competitors by undertaking such activities. When it raises its rivals’ costs, the SOE induces its profit-maximizing competitors to reduce the amount of output they choose to sell to customers and/or to increase the prices they charge for their products. These actions by competitors serve to increase customer demand for the SOE’s products, which leads to an expanded scale of operation for the SOE.

Private profit-maximizing competitors enjoy the extra profit that they can secure when their rivals are disadvantaged. If public enterprises value profit less highly than private firms, it is conceivable that they might be less likely to try to disadvantage their rivals. Quite often, though, the opposite is true. A

86. For formal analyses of such activities, see Thomas Krattenmaker & Steven Salop, Anticompetitive Exclusion: Raising Rivals’ Costs to Achieve Power Over Price, 96 YALE L.J. 299 (1986); Steven Salop, Strategic Entry Deterrence, 69 AM. ECON. REV. 415 (1979); Steven Salop & David Schefiman, Cost-Raising Strategies, 36 J. INDUS. ECON. 19 (1987); Steven Salop & David Schefiman, Raising Rivals’ Costs, 73 AM. ECON. REV. 267 (1983).
reduced focus on profit can cause an SOE to be more aggressive in raising its rivals’ costs. As noted above, a reduced focus on profit effectively can render the cost of expanded output less onerous for a public enterprise. Consequently, an SOE may be motivated to pursue the expanded scale that it values highly by reducing the output of its rivals via raising their costs.

**Conclusion 4.** An SOE will often have stronger incentives than a private, profit-maximizing firm to raise its rivals’ cost. Furthermore, these incentives for the SOE can be more pronounced the less profit-oriented is the enterprise.

Notice that when cost complementarities are present, rivals’ costs may be increased simply by the fact that they are precluded from operating in markets that are reserved exclusively for an SOE. As we explain in greater detail below, the mere presence of a reserved market can prevent rivals from reducing their costs to the level enjoyed by an SOE, even in the absence of any deliberate attempt by the SOE to raise its rivals’ costs.

In addition to raising the operating costs of an existing rival, an SOE might undertake activities designed to preclude the operation of potential rivals. For example, the SOE might lobby key policymakers to erect impenetrable entry barriers, such as statutory prohibitions on entry. When successful competitors would reduce an SOE’s ability to expand the scale and scope of its operations, the SOE will wish to limit the success of competitors. This preference often is more pronounced the more highly the SOE values expanded scale relative to profit. This observation is recorded formally as **Conclusion 5.**

**Conclusion 5.** An SOE will often have strong incentives to undertake activities designed to exclude competitors from the marketplace whenever successful competition would reduce the SOE’s output. These incentives can increase as the SOE becomes less profit-oriented.

E. **Economies of Scope between Reserved and Non-reserved Markets**

The pronounced desire of the SOE to exclude rivals reported in **Conclusion 5** arises even in the absence of cost complementarities. This desire can become more pronounced when cost complementarities are present, for the reasons identified above. In particular, when the exclusion of rivals in one market serves to increase the SOE’s output in that market, its operating costs can decline in a second market. This cost reduction, in turn, can expand the SOE’s scale of operation in the second market.

If the SOE operates both in a reserved market (such as letter delivery services) served only by the SOE and a non-reserved market (such as parcel delivery services) served by the SOE and one or more rivals, then the SOE can exploit economies of scope (cost complementarities) between the two markets. A statutory monopoly, however, truncates the range of services that an entrant can offer in competition with an SOE. The effect of the reserved area may be to prevent an efficient entrant from achieving economies of scope and thus lowering its LRAIC of supplying the *non-reserved* product. Although similar to
the “raising rivals’ costs” strategy described above, this strategy may be more accurately described as “denying rivals the opportunity to lower their costs.” In *Deutsche Post*, for example, the EC noted that “joint deliveries [of mail-order parcels and letters] create economies of scope that exist between the reserved product and the competitive product. Due to the reserved area these economies of scope are not available to competitors.” All other things remaining constant, the rival faces higher costs in the non-reserved market than the SOE experiences. We will call this the “direct effect” of the statutory monopoly in the non-reserved market.

In addition to this direct effect, an “indirect effect” may arise if economies of scale exist in the non-reserved market. If the SOE sets a lower price in the non-reserved market because of the realized economies of scope, demand will shift from the rival to the SOE. As the SOE’s output of the non-reserved product increases, the SOE experiences economies of scale that its rivals cannot achieve. The resulting decline in the SOE’s unit cost of operation in the non-reserved market may cause a further shift in sales from competitors to the SOE, depending upon the SOE’s objectives and the nature of the competitive interaction between the SOE and its rivals.

The key conclusion here is that, in the non-reserved market, the SOE may derive from its statutory monopoly over the reserved product an incremental benefit in the form of both economies of scope and economies of scale in the non-reserved market. These combined effects, direct and indirect, are not the intended consequence of the government’s having granted the SOE a statutory monopoly in the reserved market. Both incremental effects flow causally from the statutory monopoly, and not from an inherent cost advantage that only the SOE has the skill or acumen to obtain.

F. Conclusions

The diverse goals of a public enterprise can lead it to act more aggressively toward its rivals than a private enterprise. A reduced focus on profit can lead the SOE to price products below cost. It can also increase the SOE’s incentive to raise the costs of existing rivals, to erect entry barriers to preclude entry by potential rivals, and to understate costs and adopt inefficient production technologies to circumvent regulations designed to foster competition. Each of these activities can preclude the operation of more efficient competitors and thereby reduce social welfare. So, too, can the advantages that an SOE enjoys

---

87. *Deutsche Post Predatory Pricing Case*, supra note 12, at ¶ 11 n.17. The EC, however, did not draw any legal conclusion from this observation, as further analysis was not necessary in the *Deutsche Post* case. The EC had already found that Deutsche Post had abused its dominant position by pricing below the incremental cost of providing mail-order parcel service.

88. We have only analyzed selected anticompetitive activities that an SOE might undertake, and we have postulated a particular class of objectives for the SOE. We have not undertaken a comprehensive benefit-cost analysis of public enterprises. Therefore, as explained above, our analysis alone cannot provide broad policy prescriptions regarding the proper scope of SOEs. However, the fact that SOEs may have greater incentive than private enterprises to pursue anticompetitive actions suggests that the costs of public enterprises need to be weighed carefully against any benefits that such firms may provide. A comprehensive benefit-cost analysis of public enterprises would need to consider
in non-reserved markets when it, alone, is authorized to operate in reserved markets.

These findings influence the optimal design of competition law as applied to public enterprises. Because an SOE may have greater incentive to engage in anticompetitive practices and circumvent antitrust laws than its private counterpart, particular vigilance in monitoring the market activities of SOEs may be warranted. It may also be appropriate to subject an SOE to more stringent competition laws and harsher penalties for violating them.

IV. WHY STATE-OWNED ENTERPRISES MAY HAVE GREATER ABILITY THAN PRIVATE FIRMS TO ACT ANTICOMPETITIVELY

The second branch of the AKZO test provides that it is an abuse of dominant position for a firm to price below average total cost (though above average variable cost) if it does so with anticompetitive intent.\(^89\) Having found Deutsche Post liable under the first prong of the AKZO test, the EC did not apply this second standard. Because the evidence supported the conclusion that Deutsche Post’s prices were below average variable cost, an inquiry into Deutsche Post’s intent was unnecessary. Nevertheless, in a case in which the second branch of AKZO is applicable, an SOE’s status as a public enterprise would be relevant to whether the SOE had an anticompetitive intent when pricing its services below the average total cost (more precisely, the LRAIC) of producing these services.

Until relatively recently, an unstated premise in the intellectual understanding of predatory pricing had been that the alleged predator is a privately owned firm that seeks to maximize profit.\(^90\) A profit-maximizing firm will undertake predatory pricing only if doing so is expected to increase long-term profit. But a public enterprise typically does not seek to maximize long-term profit. Thus, for the reasons explained in Part III, an SOE may have greater incentive to charge below-cost prices than does a private firm.

In addition, an SOE may have expanded ability to charge below-cost prices and otherwise disadvantage competitors. There are at least five sources of this enhanced ability.

90. The implications of removing that premise are explored in LOTT, supra note 22; Lott, supra note 22; David E. M. Sappington & J. Gregory Sidak, *Are Public Enterprises the Only Credible Predators?*, 67 U. CIN. L. REV. 271 (2000); Sappington & Sidak, *Incentives for Anticompetitive Behavior by Public Enterprises*, supra note 2. For specific application to state-owned postal enterprises, see ORGANIZATION FOR ECONOMIC COOPERATION AND DEVELOPMENT, COMMITTEE ON COMPETITION LAW AND POLICY, PROMOTING COMPETITION IN POSTAL SERVICE (Series Roundtables on Competition Policy No. 24, DAFEE/CLP(99)22, Oct. 1, 1999) [hereinafter OECD REPORT ON POSTAL COMPETITION].
First, the legal framework that creates an SOE may impose upon it the duty, or confer upon it the prerogative, to pursue objectives other than profit maximization—such as the provision of universal service at a uniform, geographically averaged price. This duty or prerogative may endow an SOE with greater ability than a private, profit-maximizing firm to sustain prices below costs for extended periods of time. In its October 1999 report on competition in postal services, the Organization for Economic Cooperation and Development’s (OECD’s) Committee on Competition Law and Policy observed:

In practice the vast majority of incumbent postal operators are state-owned. The precise objectives of state-owned firms are contested, and probably differ according to the governance arrangements for state-owned firms in each country, but generally-speaking profit-maximisation is typically merely one amongst a number of objectives pursued by such firms. Where a firm, for whatever reason, does not seek to strictly maximise profits, it may be able to sustain prices below cost indefinitely, supported by either prices above cost in some other segment or by some other source of funds.

The very decision to create an SOE suggests that the firm embodies an attempt by government to rectify a perceived market failure or to advance a desired social objective, such as income redistribution, through means other than profit maximization.

Second, an SOE may not need to recoup losses by ultimately raising prices in the non-reserved market. This feature of public ownership is in direct contrast to the scholarship and jurisprudence on predatory pricing by private firms, which has emphasized that, after the exit of competitors or the prevention of entry, the dominant firm will seek to raise the price sufficiently above the competitive level for a sufficient time to recoup the earlier profit sacrifice and more. Unlike a private utility subject to rate-of-return or price-cap regulation, an SOE may have substantial ability to carry forward losses into future periods

92. OECD Report on Postal Competition, supra note 90, at 55.

95. See AKZO, supra note 26, at 1-3371 (describing predator’s interest in “eliminating competitors so as to enable it subsequently to raise its prices by taking advantage of its monopolistic position”); Brooke Group Ltd. v. Brown & Williamson Tobacco Corp., 509 U.S. 209, 221-25 (1993).
of the ratemaking process. More important, unlike a private firm, an SOE may have substantial ability to recoup its losses by raising prices in reserved markets where it has a statutory monopoly, or via direct expenditures from the public treasury. The OECD has drawn the distinction that, in the case of a public enterprise, predatory pricing is a subset of “distortionary” pricing, which does not necessarily require conventional recoupment of losses:

It is convenient . . . to label pricing below cost as “distortionary”. “Predatory” pricing is a temporary form of distortionary pricing. Even where distortionary pricing does not lead to prices subsequently being raised above cost, it may still be of public policy concern, because of the effect on productive efficiency. Distortionary pricing might induce a more efficient firm to leave or to not enter the competitive market.

This reasoning supports the conclusion that the EC should not require proof, under the second branch of the AKZO test, that an SOE intended to recoup losses through subsequent price increases.

Third, unlike the private firm that may find it impossible to repel entry when prices ultimately rise to profitable levels, SOEs may be able to preclude such entry. This ability arises because SOEs often are multiproduct firms that benefit from statutory monopolies over related products or services. The U.S. Postal Service, for example, has the discretion to interpret the contours of its own statutory monopoly. Thus, the Postal Service enjoys the ability to raise entry costs for private firms by defining the scope of non-reserved services that can be supplied privately.

Fourth, the SOE may enjoy privileges and immunities (apart from explicit state subsidies of operating losses) that facilitate recoupment of losses incurred in non-core markets or make them irrelevant. The U.S. Postal Service, for example, has no obligation to compensate its investors, the American taxpayers. The absence of an obligation to pay a competitive return on invested capital lowers the cost of funds that an SOE may use to subsidize losses in non-core markets. In addition, an SOE may be exempt from taxation, which in effect reduces its operating costs.

97. OECD REPORT ON POSTAL COMPETITION, supra note 90, at 55.
98. See IDAK & SPULBER, PROTECTING COMPETITION FROM THE POSTAL MONOPOLY, supra note 83, at 18-19, 26-31.
99. See Lars Bergman, Chris Doyle, Damien Neven & Lars-Hendrik Roller, General Principles and European Deregulation, in EUROPE’S NETWORK INDUSTRIES: CONFLICTING PRIORITIES 1, 52 (Centre for Economic Policy Research 1998) (“When most of the network firms held exclusive rights and operated largely within national territories, or were protected from competition, the provision of state aid was a matter for Member States alone. The single market programme and the commitment to opening up network industries to greater competition mean, however, that the granting of state aid is a more sensitive issue. This is particularly important when competition takes place between public and private enterprises. If a Member State grants aid to a public firm operating in a liberalized network industry, it may provide the firm with an unfair competitive advantage, and this could be considered incompatible with the common market.”).
100. See SIDAK & SPULBER, PROTECTING COMPETITION FROM THE POSTAL MONOPOLY, supra note 83, at 2, 88.
101. The U.S. Postal Service is exempt from taxation. See id. at 2.
Fifth, an SOE may be subject to less binding price regulation than is a typical private firm subject to regulation. The less binding nature of the price regulation may manifest itself in the regulatory agency’s lacking necessary powers to regulate effectively. For example, the U. S. Postal Rate Commission lacks subpoena power and has limited powers to set maximum prices for postal services. Thus, the SOE may have a heightened opportunity to engage in anticompetitive behavior, including below-cost pricing. The EC found that the letter-mail monopoly in Germany produced “a guaranteed source of income exceeding stand-alone cost” during the period covered by the Deutsche Post case. These are five of the many reasons why SOEs may have greater ability than their private, profit-maximizing counterparts to engage in anticompetitive activities. Policymakers increasingly are recognizing that this greater ability, coupled with a corresponding greater incentive of SOEs to disadvantage rivals, deserves the heightened scrutiny of competition authorities.

V. TOWARD AN APPROPRIATE PRICE FLOOR FOR THE NON-RESERVED PRODUCTS OF A STATE-OWNED ENTERPRISE

Having demonstrated that SOEs may have greater incentive and ability than profit-maximizing firms to set prices below marginal production costs and undertake other anticompetitive activities, it remains to analyze appropriate public policy to counteract these incentives. In this Part, we consider one element of such policy: the appropriate price floors for the products sold by SOEs.

Long-run average-incremental cost is the appropriate price floor for private enterprises, in part because the LRAIC price floor helps to ensure that the least-cost supplier serves customers. But we argue that LRAIC generally is too low a floor for an SOE, except in the unlikely case that the SOE has the same objective as a private, profit-maximizing firm. Thus, the question becomes, “How far above the SOE’s LRAIC should the price floor be set?” The answer to this question depends on a variety of factors that can vary across settings. The task of the ensuing discussion is to identify key relevant factors, and then to explain how they affect the selection of an appropriate price floor for an SOE.

102. This difficulty is in addition to the problem of regulating firms (public or private) in the presence of asymmetric information. See generally Jean-Jacques Laffont & Jean Tirole, A THEORY OF INCENTIVES IN PROCUREMENT AND REGULATION (MIT Press 1993).

103. See Sidak & Spulber, Protecting Competition from the Postal Monopoly, supra note 83, at 159-60; 39 U.S.C. § 3601 et seq.

104. In the United States, for example, there is a significant risk of anticompetitive cost misallocation by the U.S. Postal Service despite the fact that its independent regulator, the Postal Rate Commission, regularly presides over adversarial, evidentiary rate cases that often last nine months or more. See Sidak & Spulber, Protecting Competition from the Postal Monopoly, supra note 83, at 101-46.

105. Deutsche Post Predatory Pricing Decision, supra note 12, at 32 n.52

106. See, e.g., OECD REPORT ON POSTAL COMPETITION, supra note 90, at 55, 336-37 (Aide Memoire of the Discussion).
A. The Shortcomings of Setting the Price Floor at the SOE’s Long-Run Average-Incremental Cost

As explained above, a profit-maximizing firm will not offer a product for any substantial time at a price below its marginal cost. If it were to do so, the firm could increase its profit by reducing its output of the product. In other words, the price in that case is by definition not covering the cost incurred by the last increment in the firm’s production of the item.

The average-incremental cost of the entire product is the appropriate cost floor for a profit-maximizing firm that charges the same price to all buyers of the product in question—that is, when it does not engage in differential pricing. The justifications for using average-incremental cost as the price floor are almost precisely the same as those for using marginal cost. In particular, no competitive firm will long supply any product at a uniform price that does not cover its average-incremental cost. If $X$ is the firm’s only product, a uniform price that does not cover the average-incremental cost (AIC) of $X$ means that the firm must be losing money on that product. A private, profit-maximizing firm cannot incur such a loss indefinitely. And if the firm supplies multiple products, it could increase its total profit either by raising the price of $X$ above its AIC, or by discontinuing its supply of product $X$, whose revenues are less than the costs it causes. Thus, in the absence of differential pricing (with different units of a homogeneous product sold at different prices), predation is the only rational reason in this setting for a profit-maximizing firm to supply $X$ at a price below AIC.

In the Deutsche Post case, the EC used LRAIC as the pertinent floor by which to assess whether Deutsche Post’s pricing of parcel delivery services was predatory. Although a price floor equal to LRAIC may be appropriate for private, profit-maximizing firms, there are at least five reasons why a higher floor generally is appropriate for an SOE.

First, as demonstrated in Part III, an SOE might wish to set a price below LRAIC even in the absence of any predatory intent. A price below LRAIC can serve to expand the scale and scope of an SOE’s operations, even if the expansion entails some sacrifice of profit. Since a price below LRAIC can drive a more efficient producer from the market, it may be prudent to establish a price floor above LRAIC, particularly when incremental costs are difficult to measure perfectly. When costs are measured imperfectly, a price that exceeds measured LRAIC may nonetheless be below actual LRAIC, and thereby inhibit unduly the ability of a more efficient competitor to serve customers. A price floor above measured LRAIC can help to prevent such anticompetitive customers.

Second, as explained in Part III, SOEs may have particularly pronounced incentives to misrepresent and/or manipulate their operating costs. By doing so, SOEs may be able to evade restrictions designed to limit below-cost pricing, and thereby expand the scale and scope of their operations. A price floor in excess of LRAIC for an SOE can be prudent even if the SOE’s costs are always

107. These two paragraphs draw from BAUMOL & SIDAK, supra note 36, at 64-66.
108. Deutsche Post Predatory Pricing Case, supra note 12, at ¶¶ 6-16.
measured perfectly. This is because of the increased propensity that an SOE may have to adopt an inefficient technology and/or provide excessive quality (capacity) in order to realize low incremental costs of production, and thereby gain a competitive advantage, perhaps by circumventing restrictions on below-cost pricing. (Recall the analysis of this phenomenon in Part III.)

Third, even in the absence of any cost misrepresentation or manipulation by an SOE, its operating costs may understate the value of the social resources that it employs. For example, SOEs often enjoy privileged access to capital or are exempt from taxes or regulations that are imposed on private competitors. Consequently, even if the price that an SOE charges exceeds its subsidized LRAIC, the price may be less than the true social costs of production. In such a case, the total value that accrues to society would by increased if the SOE charged a higher price that more accurately reflected the true social costs of the firm’s operation.

Fourth, a primary reason for allowing the prices set by a private profit-maximizing firm to fall to the level of its LRAIC is to ensure that the firm can operate whenever consumers are willing to pay more for its services than it costs to produce those services. Thus, the rule helps to ensure that no opportunities to increase net industry value are precluded. But such opportunities may be limited when healthy competition among private, profit-maximizing suppliers ensures that consumers are well served. Consequently, in the presence of vigorous competition among private suppliers, the potential gains from allowing an SOE to reduce prices to the level of (measured) LRAIC may be limited, whereas the corresponding costs may be high.

Fifth, prices that merely reflect an SOE’s LRAIC do not provide any revenue in excess of the relevant costs of the SOE. Consequently, if an SOE were to establish prices equal to LRAIC for the non-core services that it supplies in non-reserved markets, the SOE’s operations in these markets would not provide net revenue (or profit) that the SOE could employ to support lower prices for its primary core services. Yet such “contribution” of net revenue to overall operations is a common justification for allowing SOEs to provide non-core services. To ensure substantial contribution to core service operations, prices significantly above LRAIC are required.

B. The Shortcomings of Setting the Price Floor to Reflect the SOE’s Hypothetical Cost Absent Its Monopoly in the Reserved Market

Competition agencies, regulators, and courts naturally gravitate toward benchmarks. If the SOE’s LRAIC is not the proper price floor, is there some other natural benchmark for the floor? One possibility comes to mind. However, this benchmark does not seem likely to provide appropriate, robust guidance across diverse settings. Efficient competitors may be deterred from operating in a non-reserved market if an SOE alone has the opportunity to exploit economies of scope in the provision of a reserved product and a non-reserved product. To counteract this artificial advantage of the SOE, the SOE might be required to set the price of the non-reserved product above the incremental cost it would incur in producing the product if there were no scope
economies with the reserved product. Under such a requirement, the relevant price floor for the SOE would not be its actual LRAIC of providing the non-reserved product. Rather, it would be the SOE’s (hypothetical) LRAIC cost of providing the non-reserved product in the absence of any scope economies between the reserved and non-reserved product.

One obvious disadvantage to the counterfactual stand-alone cost floor is that it denies a multiproduct SOE the opportunity to pass on to its customers the cost savings it derives from the economies of scope that arise in providing several services on a common infrastructure. The counterfactual cost standard also may require daunting computations. It could require predictions about equilibrium outcomes in both core and non-core markets if there were no statutory monopoly. The latter predictions would likely be particularly difficult and controversial, for they would require assumptions about how universal service obligations would be handled in the absence of a statutory monopoly. This hypothetical benchmark also fails to deliver the fundamental assurance that the SOE’s LRAIC standard provides: that the SOE is not precluded from operating when it is the least-cost supplier. Consequently, a compelling rationale for using a price floor that is unrelated to the SOE’s actual costs is not apparent.

C. How Far Above the SOE’s Long-Run Average-Incremental Cost Should the Price Floor Be Set?

We have explained why the price floor for a service that an SOE supplies in a non-reserved market should exceed the SOE’s LRAIC of delivering the service. We have also argued that it is likely to be infeasible, and it may also be analytically incorrect, to use as the price floor a counterfactual estimate of the SOE’s LRAIC absent its monopoly in the reserved market. It therefore remains to determine how far in excess of its LRAIC the price floor for an SOE should be set.

This determination requires a multi-factor analysis. The ideal distance between the SOE’s price floor and its LRAIC will depend upon at least the following six distinct considerations: (1) the incentive and ability of the SOE to pursue objectives other than profit maximization; (2) the extent to which the SOE’s LRAIC is difficult to measure accurately; (3) the degree of the SOE’s autonomy in choosing its network configuration and operating technology; (4) the nature of competition in the non-core markets in which the SOE wishes to operate; (5) the magnitude of the scope economies that the SOE enjoys because of any statutory monopoly that it is afforded in the provision of core services;
(6) the extent to which society is particularly concerned with consumers of the SOE’s core services.

Because these factors typically will differ for different SOEs, it is not possible to identify a single price floor that is ideal for all SOEs. Instead, all of these factors must be assessed carefully in establishing the extent to which the price floor for a particular SOE should exceed its LRAIC. We now proceed to explain the importance of each of these factors.

1. The SOE’s Objectives

The more able and the more inclined is an SOE to expand the scale and scope of its operations rather than to maximize the profit it generates, the higher should be the price floor established for the SOE. As explained in Part III, the more concerned is the SOE with the scale and scope of its operations, the more inclined it will be to set below-cost prices, even if doing so entails the strategic manipulation of accounting costs and the implementation of inefficient operating technologies. The harms from such activities can be mitigated to some extent by raising the SOE’s price floor substantially above its LRAIC. In particular, the higher price floor can reduce the likelihood that an SOE will drive a more efficient private competitor from the market, or otherwise unduly limit the ability of the competitor to serve customers.

In practice, the mandates of the SOE and its historic performance can provide useful information about its objectives. An SOE that is not charged with generating revenue in excess of operating costs and that consistently incurs substantial deficits with little or no public outcry may well have considerable incentive to pursue objectives other than profit maximization. An SOE that has aggressively pursued operations beyond the provision of its core monopoly services may also be one that has particular concern with expanding the scale and scope of its operations.

2. Measurement Difficulties

The price floors for an SOE should also be raised further above its measured LRAIC the more difficult it is to measure the SOE’s costs accurately. When costs are difficult to measure accurately (either for unavoidable technological reasons or because the SOE has strong incentive and ability to misrepresent actual costs), measured costs may depart significantly from actual costs. Consequently, even if prices exceed measured LRAIC, they may fall below actual LRAIC. Higher price floors can help to limit such outcomes and the associated harms to competition.

In practice, several factors are likely to influence the prevailing difficulty in measuring an SOE’s costs accurately. These factors include: (1) the resources that a regulatory body devotes to assessing costs; (2) the expertise and experience of the regulatory body; (3) the SOE’s autonomy in keeping its books of account and in preparing cost estimates; and (4) the similarity of the SOE’s operating conditions and operating technology to the corresponding conditions and technologies that are commonly employed and measured in other
jurisdictions. The historical accuracy of past cost estimates can often serve as a useful practical indicator of the likely accuracy of future cost measurements.

3. **The SOE’s Autonomy**

As explained in Part III, SOEs may have strong incentives to choose inefficient production technologies in order to avoid binding restrictions on below-cost pricing. When this strong incentive is accompanied by considerable autonomy to select production technologies and operating procedures, higher cost floors can be appropriate. This autonomy for the SOE might manifest itself, for example, in the form of limited regulatory control over the SOE’s investments and limited regulatory investigation of the efficiency of the SOE’s operations.

4. **Competition in Non-core Markets**

When an SOE expands its operations beyond the production of basic core services (such as the ubiquitous delivery of letters), the SOE may be able to enhance the welfare of consumers of non-core services (such as the delivery of large parcels). The likely extent of such welfare enhancement typically will vary according to the extent of competition among other suppliers of non-core services. When intense competition among other suppliers produces high-quality services and low prices for consumers, the potential increase in consumer welfare that is likely to result from the SOE’s operation in the market may be limited. Under such circumstances, higher floors for the prices that the SOE sets for non-core services may be justified. The higher price floors can help to ensure that more efficient providers of non-core services are not driven from the market or otherwise unduly restricted from serving customers. And, under the identified circumstances, the higher price floors introduce limited risk of substantial harm to consumers of non-core services.

5. **Economies of Scope**

Higher price floors for the SOE’s non-core services can also be appropriate when pronounced economies of scope exist in the provision of core and non-core services. When these scope economies are large, the SOE’s LRAIC of producing non-core services will be relatively low. These low costs will arise simply because the SOE enjoys a statutory monopoly in the provision of core services, not because of any inherent technological or operational superiority on the part of the SOE. Consequently, if price floors for the SOE simply reflect its LRAIC of producing non-core services, the SOE will be afforded considerable opportunity to drive private suppliers of non-core services from the market, even though those suppliers are operating efficiently and could produce all services at lower cost than the SOE if they were permitted to provide core services.

Thus, with price floors set at the level of LRAIC in the presence of substantial economies of scope, an SOE may be afforded substantial opportunity to extend the scope of its operations well beyond the core services.
that may have constituted its original charter. The SOE may also be given considerable latitude to drive from non-core markets private suppliers that might otherwise discipline and constrain the non-core operations of the SOE. Price floors above LRAIC for the SOE can promote private competition over public production and provide additional checks on the operations of SOEs.

6. Concern With Core Customers

As noted above, price floors set at the level of LRAIC do not guarantee that an SOE’s operations in non-core markets provide any benefit to core customers. Only if the SOE’s prices for non-core services exceed its LRAIC of producing those services will non-core operations produce net revenues (or profit) that can be employed to reduce the prices of core services while maintaining prevailing levels of profitability for the SOE. As long as the SOE’s prices are not forced above profit-maximizing levels in non-core markets, higher price floors will ensure that the SOE’s operations in non-core markets generate greater net revenue for the SOE. This enhanced net revenue can be particularly valuable when it is deemed particularly important to ensure low prices for core services, perhaps because universal subscription to core services has substantial social value and/or because many customers of core services have limited wealth.

7. Summary

These six factors are among the central considerations that determine the extent to which the floors on prices charged by an SOE in non-core markets would exceed the SOE’s LRAIC of producing the non-core products. The preceding analysis reveals that the extent to which price floors should exceed an SOE’s LRAIC varies with the SOE’s objectives, capabilities, and operating conditions. Consequently, no simple formulae are available that specify ideal price floors for every conceivable set of circumstances. However, reasonable price floors can be established in any particular setting through judicious consideration of the factors identified above.

VI. Conclusion

Competition law for state-owned enterprises is virtually nonexistent in American jurisprudence. However, the EC’s decision in the Deutsche Post case in 2001 has already established an important precedent, one that may soon have an effect on the United States if it informs the analysis of the arbitration panel in the Canada Post case filed under Chapter 11 of NAFTA. The challenge ahead is to infuse emerging legal principles in such cases with sound economic analysis that reflects the special characteristics of public enterprises and the network industries in which SOEs commonly operate.

Our economic analysis has shown that SOEs may have strong incentives to engage in anticompetitive activities that serve to expand the scale and scope of their operations. When an SOE values both profit and expanded scale, it will
discount the cost of output expansion. Consequently, even though such an SOE values the profit that its anticompetitive activities can generate less highly than does a private profit-maximizing firm, the SOE will find it optimal to pursue aggressively anticompetitive activities that expand the scale of its operations. In particular, an SOE may set prices below marginal production costs, particularly on products for which demand is price-elastic. An SOE also may understate its marginal cost of production and overinvest in capacity in order to relax a binding prohibition on pricing below cost. In addition, an SOE may have stronger incentives than a private, profit-maximizing firm to raise its rivals’ costs and to undertake activities designed to exclude rivals from relevant markets. An SOE’s incentive to undertake such anticompetitive activities generally increases as the SOE’s concern with profit decreases and its concern with expanded scale and scope increases.

SOEs also commonly have an enhanced ability to engage in anticompetitive activities relative to private firms. The enhanced ability stems from several sources. For example, SOEs often enjoy privileges and immunities that afford them considerable discretion in the activities they undertake. In addition, an SOE’s legal framework may impose upon it the duty, or confer upon it the prerogative, to pursue objectives other than profit maximization. Furthermore, SOEs often are multiproduct firms that benefit from statutory monopolies over related products. Consequently, SOEs, unlike their private competitors, may not need to recoup the costs of anticompetitive activities by raising prices in non-reserved markets.

In light of the greater incentive and ability of SOEs to engage in anticompetitive activities, we recommend higher price floors in non-reserved markets for SOEs that enjoy a statutory monopoly in a reserved market. In particular, we recommend price floors that exceed the SOE’s long-run average-incremental cost (LRAIC) of production. The extent to which the price floor should exceed the SOE’s LRAIC will depend upon a variety of factors, including the incentive and ability of the SOE to pursue objectives other than profit maximization, the extent to which the SOE’s LRAIC is difficult to measure, and the magnitude of the scope economies that the SOE enjoys because of its statutory monopoly in a reserved market. These factors differ for different SOEs, and thus the most appropriate price floor generally will differ for different SOEs.
